

Calculating A Survey's Design Effect Due To Unequal Selection Probabilities

James Wyatt

The Design Effect

Can be defined:

$$DEFF = \frac{\sum_{i=1}^n w_i^2}{(\sum_{i=1}^n w_i)^2 * n}$$

After weighting for complex sampling, you sum the squared weights and divided it by the sum of the weights squared and multiply by the sample size.

After calculating the MOE:

$$MoE = z * \sqrt{\frac{p(1-p)}{n}}$$

or using an approximation:

$$MoE = \frac{.98}{\sqrt{n}}$$

you can update your level of precision of survey findings by incorporating the *DEFF* & *MoE* by taking the square root of the *DEFF* (otherwise known as the *DEFFT*) and multiplying it with the *Mo*

The confidence interval can then be expressed:

$$\sqrt{(DEFF) * MoE}$$
